

Round 7 · exact local fluctuations retain the chosen input

New arithmetic implementation of established conditional-variance tools; independently checked through $q = 6,700,417$.

A Available summaries can still lose information

A: complete normalized Paley17 scans; the six-point shortcut fails at $n = 7$ and 8 . Zero observed ambiguity is not a general sufficiency theorem.

B: exact local moments plus classical Cantelli; $n = 6, 16, 31, 50$. These bounds concern individual one-swap neighbourhoods, not all sets or multiple steps.

B One-step persistence on selected critical-size inputs
