

Round 8 · keep the insertion shared across deletion choices

Exact covariance distinguishes actual inputs whose complete edit marginals agree; a separate control removes the common response.

A Equal marginal laws, different edit coupling

A: all one-swap values and the unlabelled per-deletion distributions agree; the per-insertion distributions differ. This toy is outside $n^4 \leq q$.

B: reference = $25 / [25 + (n-1)(n-5)^2]$ for independent signs. It is not a Paley law; these are eight selected inputs at $n = 6, 16, 31, 50$.

B Compare against an explicit common-mode baseline
